

From lectures 7, 8 and 9: We learned how salts and gases can dissolve in seawater and their importance for the marine environment. Specifically, excess of Carbon Dioxide can reduce the water's pH and becoming harmful for corals and other organisms. Can we consider anthropogenic CO₂ as a pollutant? Let's find out.

Lecture Session 8

1. Define and discuss what marine pollutants are;
2. Examples of marine pollution;
3. Impacts and solutions.

Icebreaker discussion. In groups ...

1. Each group will identify three anthropogenic influences on the marine environment
2. Each group will take a turn sharing their information with the class and writing them on a board or in the zoom chat.
3. Discuss ways to categorize the anthropogenic influences into groups based on similarities

An aerial photograph of a tropical coastline. A narrow, white sandy beach runs diagonally across the frame, separating a shallow, turquoise lagoon from a deeper, dark blue ocean. The lagoon is filled with dense, green coral reefs. In the upper right, there are patches of white sand or coral bleaching. The overall scene is serene but carries an underlying message of environmental concern.

Marine Pollution

Marine pollutants may be natural or human-generated

- **Marine pollution** – affects the physical, chemical, or biological environment
- Pollution can be **chronic** or **acute**
- Pollutants interfere with mechanical or biological processes in an organism. The effects will depend on the pollutant's
 - Quantity
 - Toxicity
 - Persistence

Tom Garrison

Icebreaker discussion 2. In groups ...

1. Each group will identify one natural pollution source
2. Each group will take a turn sharing their information with the class and writing them on a board or in the zoom chat.

Icebreaker discussion 2. In groups ...

1. Each group will identify one natural pollution source
2. Each group will take a turn sharing their information with the class and writing them on a board or in the zoom chat.

Few examples: Volcanic activity, natural eutrophication, natural oil seeps, natural harmful algal blooms, intense changes to oceanographic conditions (Ex: intense upwelling events).

Main sources of human-generated marine pollutants

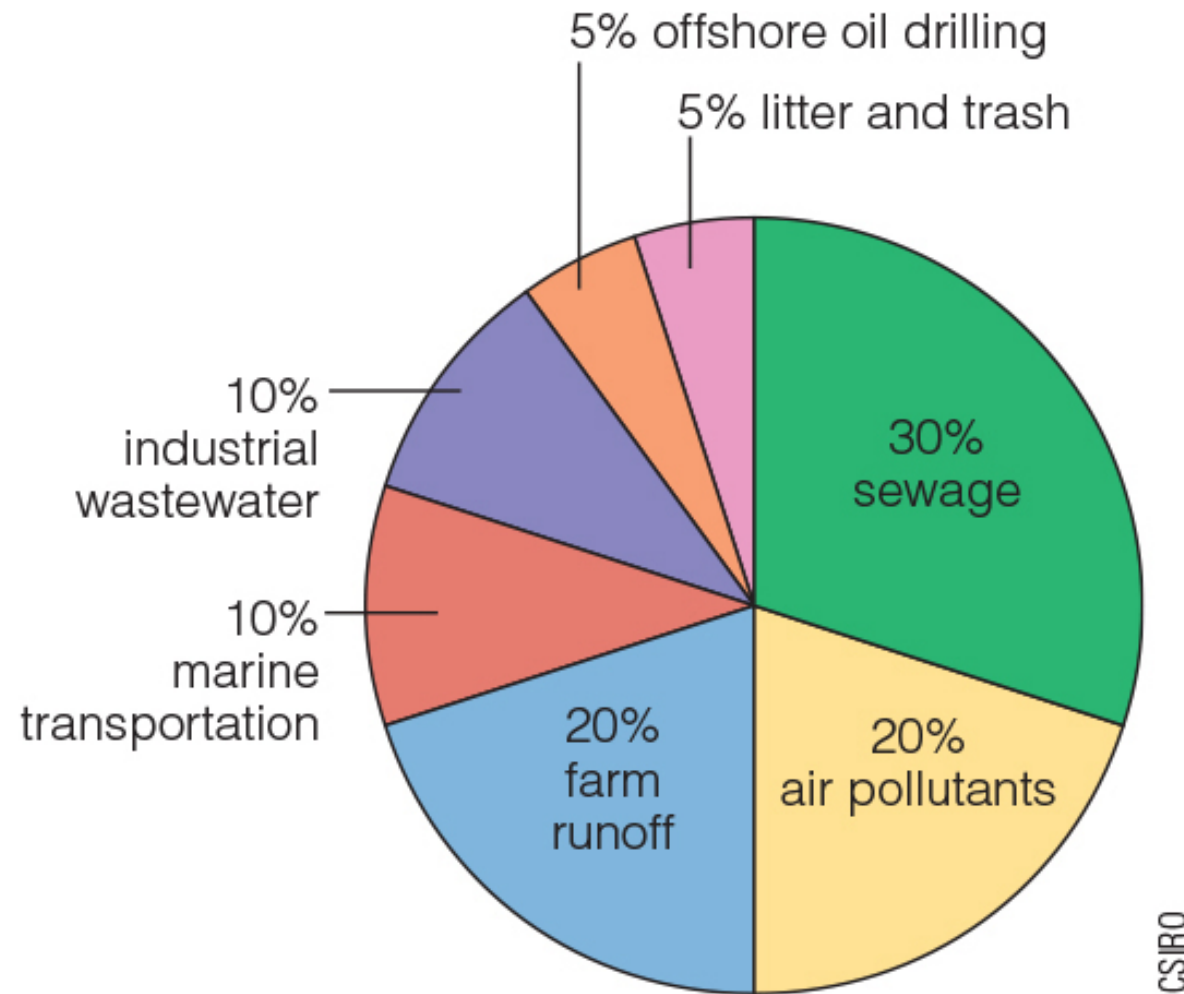

Figure 18.2 Sources of marine pollution.

An aerial photograph of a coastline. The ocean is a deep, dark blue. Along the shore, there is a large, irregular spill of dark, viscous material, likely oil, which has spread across the beach and into the shallow water. The spill is dark brown/black, contrasting sharply with the lighter green and yellowish-brown of the beach and the clear water. The text "Oil in the ocean" is overlaid in white, sans-serif font in the center of the image.

Oil in the ocean

Natural oil seeps is the major source of crude oil to the marine environment. However, its chronic, constant, and small spread out nature makes it less “impacting”.

- Natural oil seeps: crude oil
- Human-caused oil in the ocean
 - Crude oil
 - Refined oil

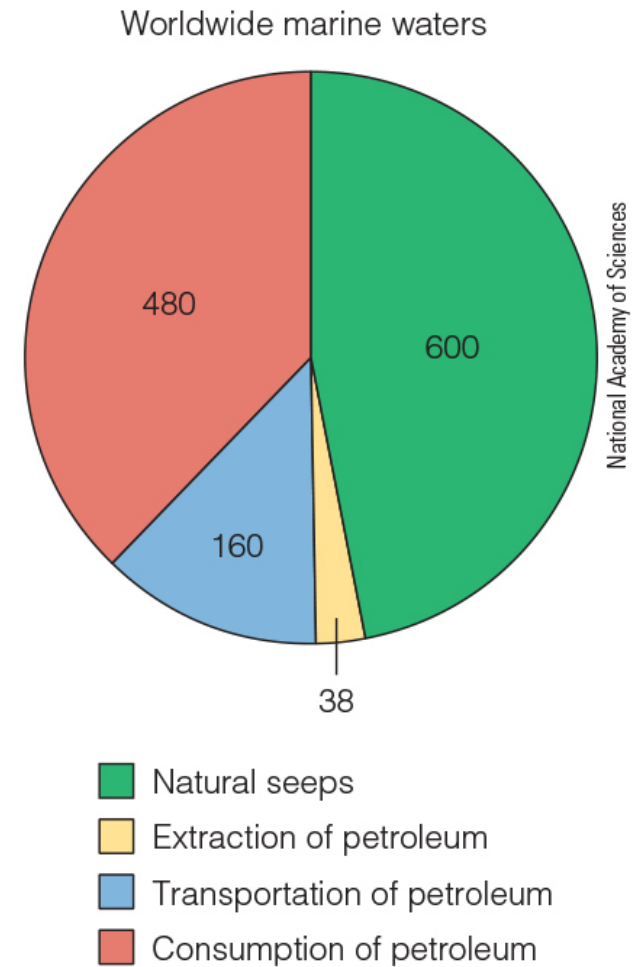

Figure 18.3 Average worldwide annual releases of petroleum by source (1990–1999), in thousands of metric tons per year.

Oil Spills

Acute pollution source with long-lasting environmental and economic impacts

Figure 18.6 The fate of oil spilled at sea.

Smaller molecules evaporate or dissolve into the water beneath the slick. Within a few days, water motion coalesces the oil into tar balls and semisolid emulsions of water in oil and oil in water. Tar balls and emulsions may persist for months after formation. If crude oil is left undisturbed, bacterial activity will eventually consume it. Refined oil, however, can be more toxic, and natural cleaning processes take a proportionally longer time to complete.

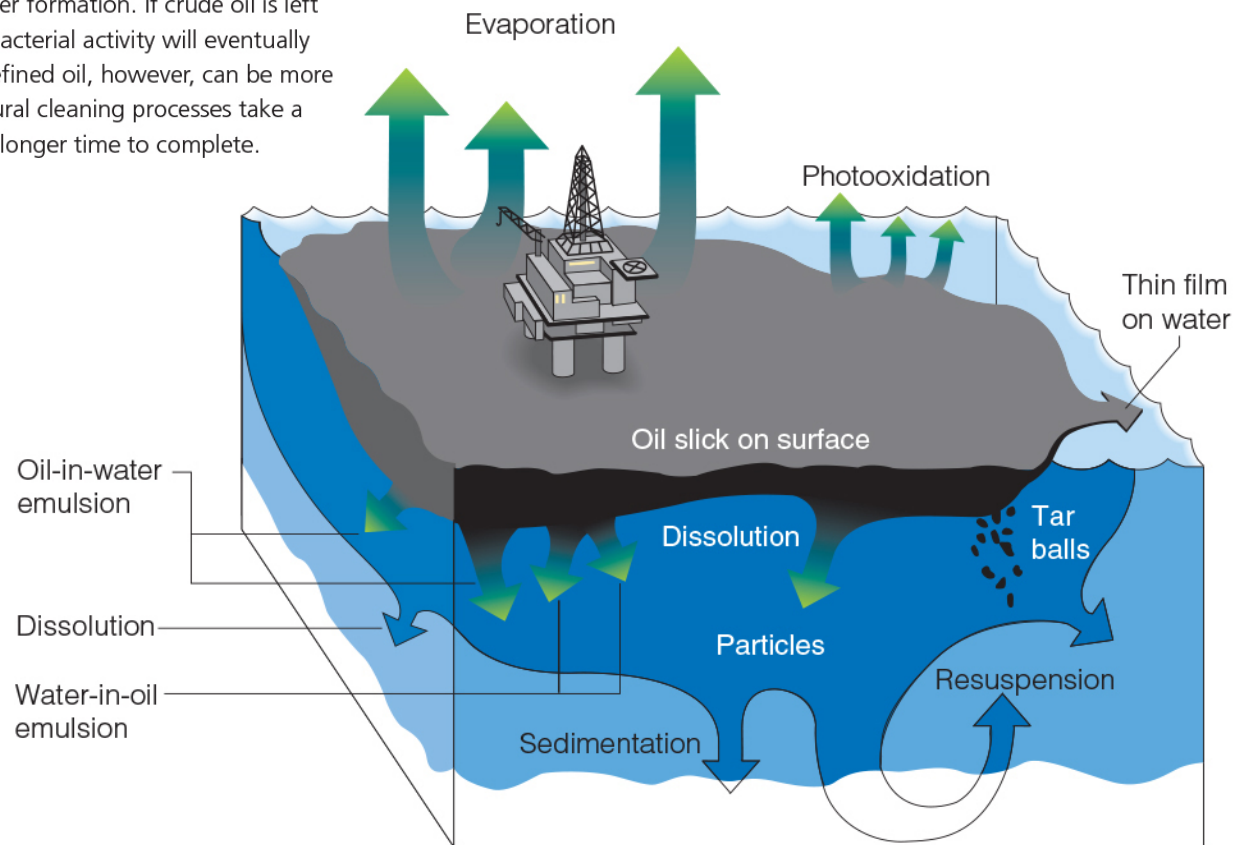

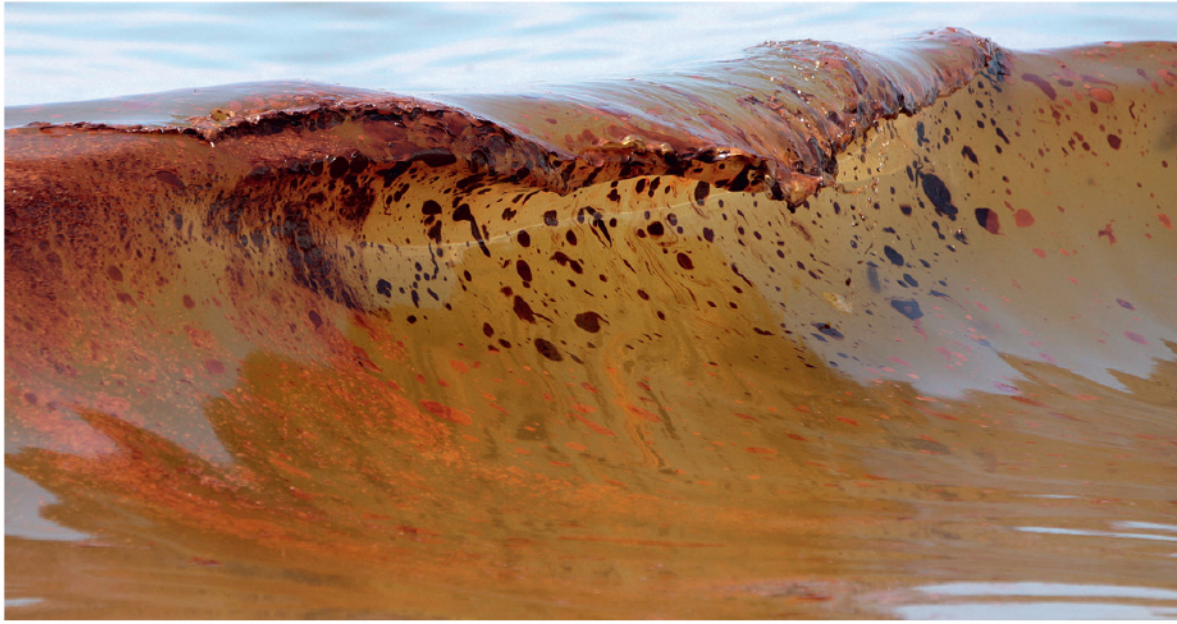

Figure 18.8 Deepwater Horizon moments before sinking.

AP Images/Dave Martin

- a** Congealed crude oil washes up on Orange Beach, Alabama, about 145 kilometers (90 miles) from the site of the *Deepwater Horizon* spill.

- b** An oil-soaked brown pelican being rescued from the fouled marshlands of Louisiana nearly a month and a half after the *Deepwater Horizon* spill.

UPI/Alamy Stock Photo

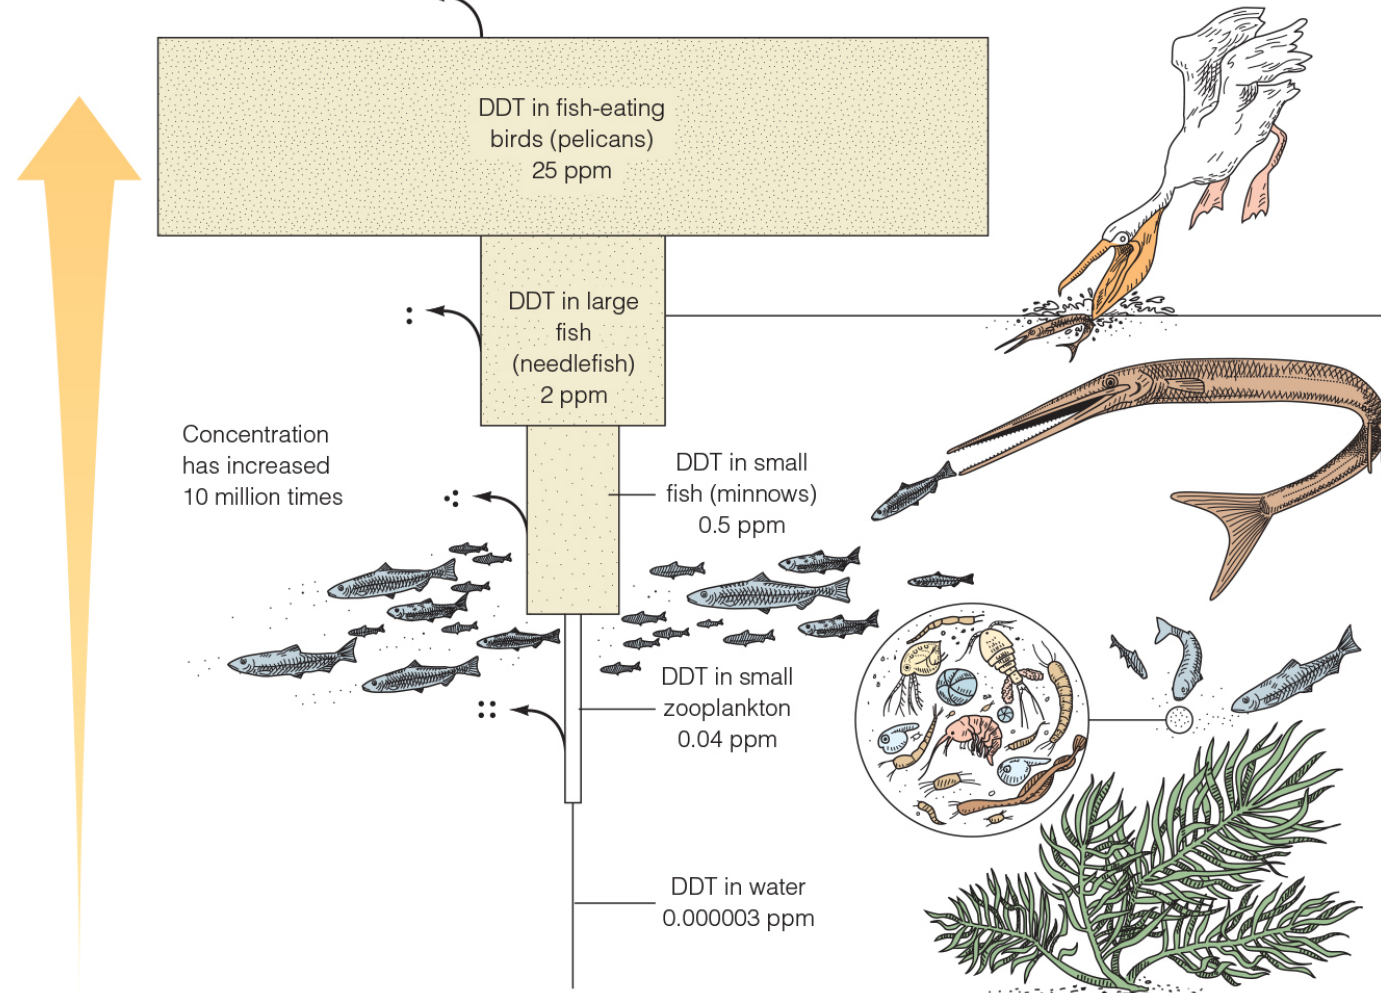

Figure 18.5 Crude oil spills.

An aerial photograph of a coastal area. The top half of the image shows a deep blue ocean. Below the ocean is a narrow strip of land with a greenish-brown, textured surface, possibly a reef flat or mangrove area. A thin, light-colored sandy beach runs along the edge of this land. The bottom half of the image shows a vast, flat, greenish-brown landscape, likely a grassy field or wetland. The text "Bioaccumulation of toxic chemicals" is overlaid in white, sans-serif font, centered horizontally and positioned in the upper-middle part of the image.

Bioaccumulation of toxic chemicals

Heavy metals 🤘 (Ex: mercury, lead), pesticides, and plastic can bioaccumulate (biomagnification) along the food chain

An aerial photograph of a tropical coastline. The top half of the image shows deep blue ocean water. Below this is a vibrant turquoise reef flat with visible coral patterns. A narrow strip of white sand beach separates the reef from a lush green land area. The bottom half of the image is dominated by the dense green vegetation of the land.

Plastic (maybe the worst of all)

Toxic plastic chemical components can also bioaccumulate. Plastic has been released in the marine environment over several decades (chronic pollutant) with no regulation so far. It can break down into very small pieces (pallets) impacting all sorts of organisms.

A LIFETIME OF PLASTIC

The first plastics made from fossil fuels are just over a century old. They came into widespread use after World War II and are found today in everything from cars to medical devices to food packaging. Their useful lifetime varies. Once disposed of, they break down into smaller fragments that linger for centuries.

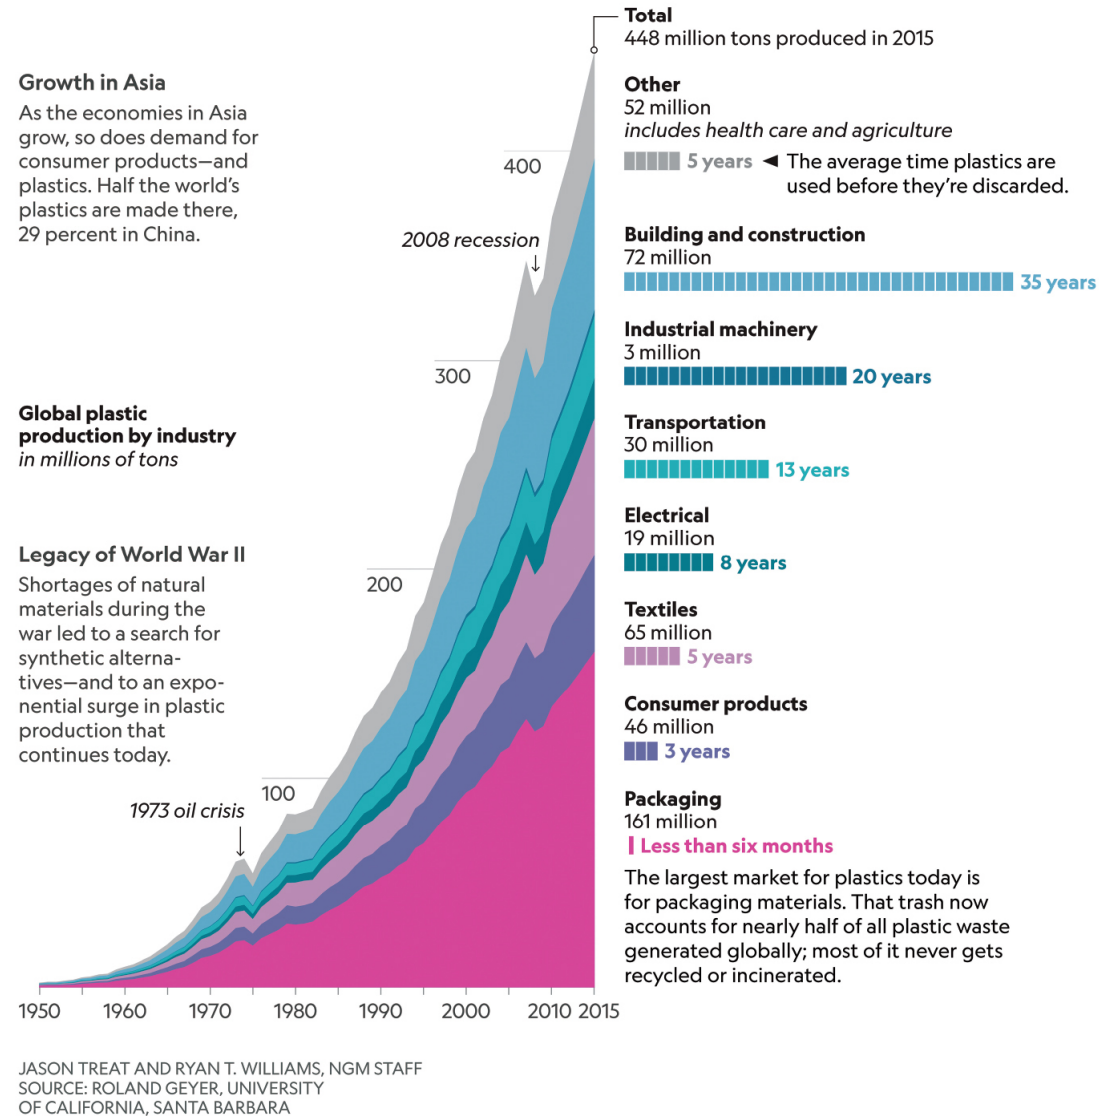

Figure 18.15 The amount of plastic produced over the last half century has risen nearly exponentially.

It impacts from large organisms

Figure 18.16 A bottlenose dolphin swims through a sea of marine debris dominated by plastic waste.

a Sea lions (seen here) and seals die by the hundreds each year after becoming entangled in plastic debris, especially discarded and broken fishing nets.

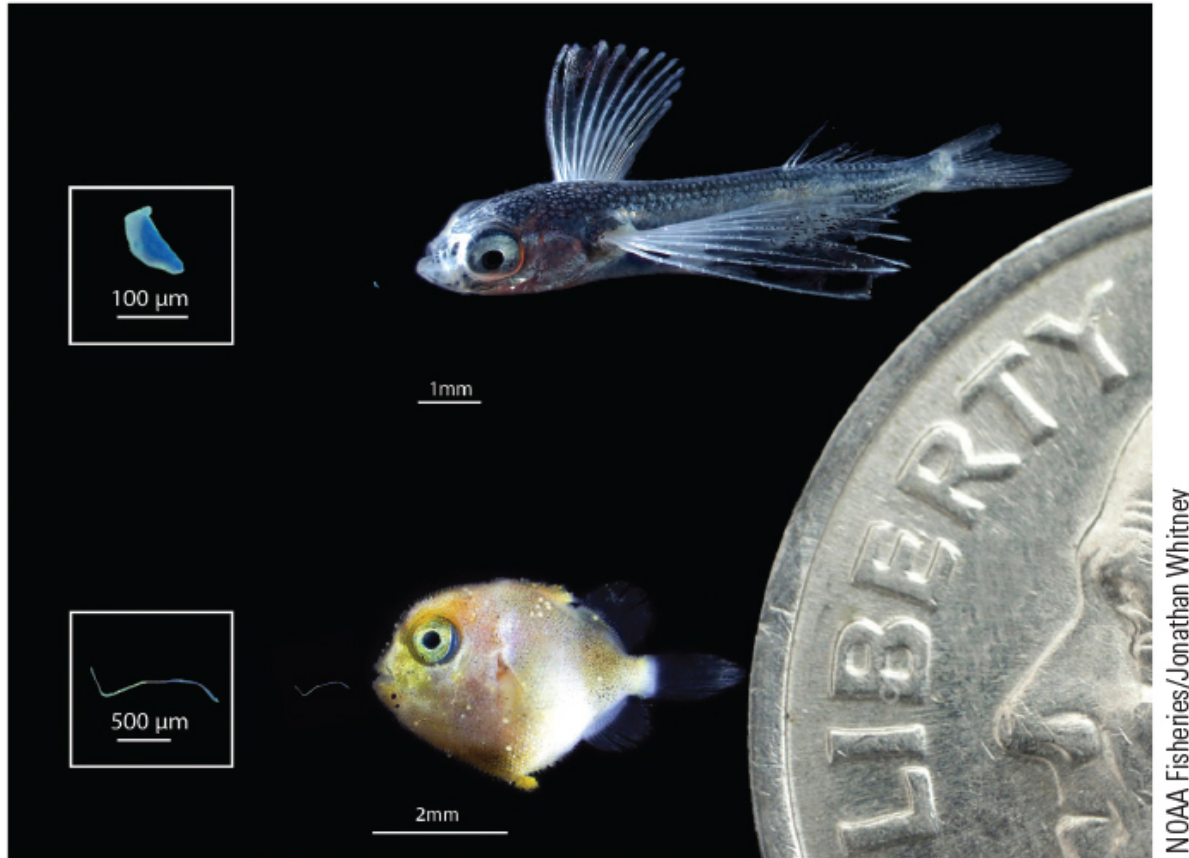

b A decaying albatross reveals the cause of its death. Plastic trash (mistaken for food) has blocked its digestive system. On Midway Atoll, about 40% of albatrosses die in this way.

c Some species of sea turtles can mistake floating plastic bags for their natural food source, jellies.

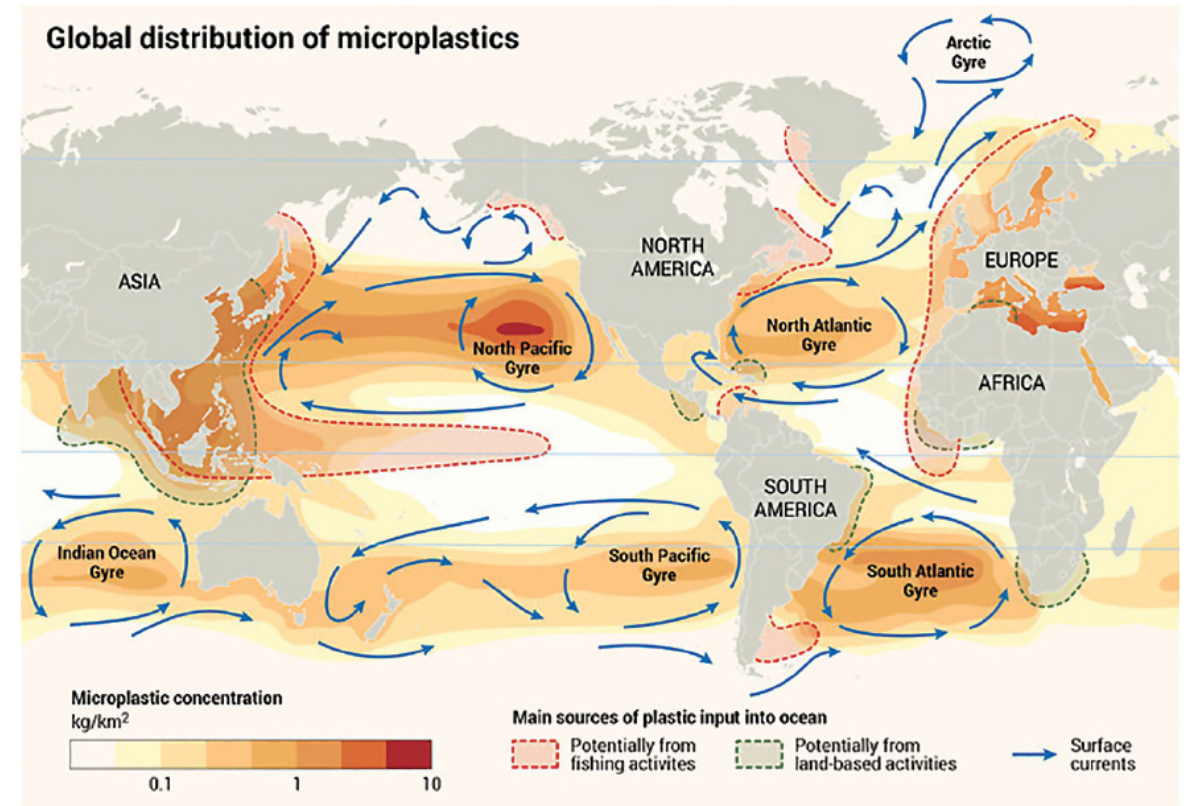

Figure 18.17 Discarded plastic can pose direct or indirect dangers to marine life.

To the smallest everywhere in the ocean

- b** Larval fish have been found to ingest toxin-laden microplastics at a stage in their life history that is critical to their development. The dime on the right side of the image is shown for scale.

Ocean circulation spreads plastics around

- c** The global distribution of microplastics. Note their concentration and distribution in relationship to the major gyres and that the primary sources from fishing activities and land-based activities overlap in some areas and are different in others.
